## DATA SHEET

## TEA1094; TEA1094A Hands free IC

File under Integrated Circuits, IC03

## FEATURES

- Low power consumption
- Power-down function (TEA1094A only)
- Microphone channel with:
- externally adjustable gain
- microphone mute function.
- Loudspeaker channel with:
- externally adjustable gain
- dynamic limiter to prevent distortion
- rail-to-rail output stage for single-ended load drive
- logarithmic volume control via linear potentiometer
- loudspeaker mute function.
- Duplex controller consisting of:
- signal envelope and noise envelope monitors for both channels with:
externally adjustable sensitivity
externally adjustable signal envelope time constant externally adjustable noise envelope time constant
- decision logic with:
externally adjustable switch-over timing externally adjustable idle mode timing externally adjustable dial tone detector in receive channel
- voice switch control with:
adjustable switching range
constant sum of gain during switching
constant sum of gain at different volume settings.

## APPLICATIONS

- Mains, battery or line-powered telephone sets with hands-free/listening-in functions
- Cordless telephones
- Answering machines
- Fax machines.

## GENERAL DESCRIPTION

The TEA1094 and TEA1094A are bipolar circuits intended for use in mains, battery or line-powered telephone sets, cordless telephones, answering machines and Fax machines. In conjunction with a member of the TEA106X, TEA111X families of transmission circuits, the devices offer a hands-free function. They incorporate a microphone amplifier, a loudspeaker amplifier and a duplex controller with signal and noise monitors on both channels.

ORDERING INFORMATION

| TYPE NUMBER | PACKAGE |  |  |
| :--- | :---: | :--- | :---: |
|  | NAME | DESCRIPTION | VERSION |
| TEA1094 | DIP28 | plastic dual in-line package; 28 leads (600 mil) | SOT117-1 |
| TEA1094A | DIP24 | plastic dual in-line package; 24 leads (600 mil) | SOT101-1 |
| TEA1094T | SO28 | plastic small outline package; 28 leads; body width 7.5 mm | SOT136-1 |
| TEA1094AT | SO24 | plastic small outline package; 24 leads; body width 7.5 mm | SOT137-1 |
| TEA1094AM | SSOP24 | plastic shrink small outline package; 24 leads; body width 5.3 mm | SOT340-1 |

## FUNCTIONAL DESCRIPTION

## General

The values given in the functional description are typical values unless otherwise specified.
A principle diagram of the TEA106X is shown on the left side of Fig.4. The TEA106X is a transmission circuit of the TEA1060 family intended for hand-set operation. It incorporates a receiving amplifier for the earpiece, a transmit amplifier for the microphone and a hybrid. For more details on the TEA1060 family, please refer to "data Handbook IC03". The right side of Fig. 4 shows a principle diagram of the TEA1094 and TEA1094A, hands-free add-on circuits with a microphone amplifier, a loudspeaker amplifier and a duplex controller.

As can be seen from Fig.4, a loop is formed via the sidetone network in the transmission circuit and the acoustic coupling between loudspeaker and microphone of the hands-free circuit. When this loop gain is greater than 1, howling is introduced. In a full duplex application, this would be the case.
The loop-gain has to be much lower than 1 and therefore

Fig. 3 Pin configuration (TEA1094A).
has to be decreased to avoid howling. This is achieved by the duplex controller. The duplex controller of the TEA1094 and TEA1094A detects which channel has the 'largest' signal and then controls the gain of the microphone amplifier and the loudspeaker amplifier so that the sum of the gains remains constant.
As a result, the circuit can be in three stable modes:

1. Transmit mode (Tx mode).

The gain of the microphone amplifier is at its maximum and the gain of the loudspeaker amplifier is at its minimum.
2. Receive mode (Rx mode).

The gain of the loudspeaker amplifier is at its maximum and the gain of the microphone amplifier is at its minimum.
3. Idle mode.

The gain of the amplifiers is halfway between their maximum and minimum value.

The difference between the maximum gain and minimum gain is called the switching range.

Fig. 4 Hands-free telephone set principles.

## Supply: pins $\mathrm{V}_{\mathrm{BB}}$, GND and PD

The TEA1094 and TEA1094A must be supplied with an external stabilized voltage source between pins $\mathrm{V}_{\mathrm{BB}}$ and GND. In the idle mode, without any signal, the internal supply current is 3.1 mA at $\mathrm{V}_{\mathrm{BB}}=5 \mathrm{~V}$.

To reduce the current consumption during pulse dialling or register recall (flash), the TEA1094A is provided with a power-down (PD) input. When the voltage on PD is HIGH the current consumption from $V_{B B}$ is $180 \mu \mathrm{~A}$.

## Microphone channel: pins MIC, GAT, MOUT, MICGND and MUTET (see Fig.5)

The TEA1094 and TEA1094A have an asymmetrical microphone input MIC with an input resistance of $20 \mathrm{k} \Omega$. The gain of the input stage varies according to the mode of the TEA1094 and TEA1094A. In the transmit mode, the gain is at its maximum; in the receive mode, it is at its minimum and in the idle mode, it is halfway between maximum and minimum.

Switch-over from one mode to the other is smooth and click-free. The output capability at pin MOUT is $20 \mu \mathrm{~A}$ (RMS).
In the transmit mode, the overall gain of the microphone amplifier (from pins MIC to MOUT) can be adjusted from 0 dB up to 31 dB to suit specific application requirements. The gain is proportional to the value of $\mathrm{R}_{\mathrm{GAT}}$ and equals 15.5 dB with $\mathrm{R}_{\mathrm{GAT}}=30.1 \mathrm{k} \Omega$.

A capacitor must be connected in parallel with $\mathrm{R}_{\mathrm{GAT}}$ to ensure stability of the microphone amplifier. Together with $R_{G A T}$, it also provides a first-order low-pass filter.
By applying a HIGH level on pin MUTET, the microphone amplifier is muted and the TEA1094 and TEA1094A are automatically forced into the receive mode.

The pin numbers given in parenthesis refer to the TEA1094A.
Fig. 5 Microphone channel.

## Loudspeaker channel

The pin numbers given in parenthesis refer to the TEA1094A.

Fig. 6 Loudspeaker channel.

Loudspeaker amplifier: pins RiN1, RIN2, GAR and LSP
The TEA1094 and TEA1094A have symmetrical inputs for the loudspeaker amplifier with an input resistance of $40 \mathrm{k} \Omega$ between RIN1 and RIN2 $(2 \times 20 \mathrm{k} \Omega)$. The input stage can accommodate signals up to 390 mV (RMS) at room temperature for $2 \%$ of total harmonic distortion (THD). The gain of the input stage varies according to the mode of the TEA1094 and TEA1094A. In the receive mode, the gain is at its maximum; in the transmit mode, it is at its minimum and in the idle mode, it is halfway between maximum and minimum. Switch-over from one mode to the other is smooth and click-free. The rail-to-rail output stage is designed to power a loudspeaker connected as a single-ended load (between LSP and GND).
In the receive mode, the overall gain of the loudspeaker amplifier can be adjusted from 0 dB up to 33 dB to suit specific application requirements. The gain from RIN1 and RIN2 to LSP is proportional to the value of $R_{G A R}$ and equals 18.5 dB with $\mathrm{R}_{\mathrm{GAR}}=66.5 \mathrm{k} \Omega$. A capacitor connected in parallel with $\mathrm{R}_{\mathrm{GAR}}$ can be used to provide a first-order low-pass filter.

## Volume control: pin VOL

The loudspeaker amplifier gain can be adjusted with the potentiometer R Vol. A linear potentiometer can be used to obtain logarithmic control of the gain at the loudspeaker amplifier. Each $950 \Omega$ increase of $R_{\text {VoL }}$ results in a gain loss of 3 dB . The maximum gain reduction with the volume control is internally limited to the switching range.

## DYNAMIC LIMITER: PIN DLC//MUTER

The dynamic limiter of the TEA1094 and TEA1094A prevents clipping of the loudspeaker output stage and protects the operation of the circuit when the supply voltage at $\mathrm{V}_{\mathrm{BB}}$ falls below 2.9 V .

Hard clipping of the loudspeaker output stage is prevented by rapidly reducing the gain when the output stage starts to saturate. The time in which gain reduction is effected (clipping attack time) is approximately a few milliseconds. The circuit stays in the reduced gain mode until the peaks of the loudspeaker signals no longer cause saturation. The gain of the loudspeaker amplifier then returns to its normal value within the clipping release time (typically 250 ms ). Both attack and release times are proportional to the value of the capacitor $\mathrm{C}_{\text {DLC }}$. The total harmonic distortion of the loudspeaker output stage, in reduced gain mode, stays below $5 \%$ up to 10 dB (minimum) of input voltage overdrive [providing $\mathrm{V}_{\text {RIN }}$ is below 390 mV (RMS)].

When the supply voltage drops below an internal threshold voltage of 2.9 V , the gain of the loudspeaker amplifier is rapidly reduced (approximately 1 ms ). When the supply voltage exceeds 2.9 V , the gain of the loudspeaker amplifier is increased again.
By forcing a level lower than 0.2 V on pin DLC/ $\overline{M U T E R}$, the loudspeaker amplifier is muted and the TEA1094 (TEA1094A) is automatically forced into the transmit mode.

## Duplex controller

Signal and noise envelope detectors: pins TSEN, TENV, TNOI, RSEN, RENV and RNOI

The signal envelopes are used to monitor the signal level strength in both channels. The noise envelopes are used to monitor background noise in both channels. The signal and noise envelopes provide inputs for the decision logic. The signal and noise envelope detectors are shown in Fig.7.
For the transmit channel, the input signal at MIC is 40 dB amplified to TSEN. For the receive channel, the differential signal between RIN1 and RIN2 is 0 dB amplified to RSEN. The signals from TSEN and RSEN are logarithmically compressed and buffered to TENV and RENV respectively. The sensitivity of the envelope detectors is set with $R_{\text {TSEN }}$ and $R_{\text {RSEN }}$. The capacitors connected in series with the two resistors block any DC component and form a first-order high-pass filter. In the basic application, see Fig.13, it is assumed that $\mathrm{V}_{\text {MIC }}=1 \mathrm{mV}$ (RMS) and $\mathrm{V}_{\text {RIN }}=100 \mathrm{mV}$ (RMS) nominal and both $R_{\text {TSEN }}$ and $R_{\text {RSEN }}$ have a value of $10 \mathrm{k} \Omega$. With the value of $\mathrm{C}_{\text {TSEN }}$ and $\mathrm{C}_{\text {RSEN }}$ at 100 nF , the cut-off frequency is at 160 Hz .

The buffer amplifiers leading the compressed signals to TENV and RENV have a maximum source current of $120 \mu \mathrm{~A}$ and a maximum sink current of $1 \mu \mathrm{~A}$. Together with the capacitor $\mathrm{C}_{\text {TENV }}$ and $\mathrm{C}_{\text {RENV }}$, the timing of the signal envelope monitors can be set. In the basic application, the value of both capacitors is 470 nF . Because of the logarithmic compression, each 6 dB signal increase means 18 mV increase of the voltage on the envelopes TENV or RENV at room temperature. Thus, timings can be expressed in $\mathrm{dB} / \mathrm{ms}$. At room temperature, the $120 \mu \mathrm{~A}$ sourced current corresponds to a maximum rise-slope of the signal envelope of $85 \mathrm{~dB} / \mathrm{ms}$. This is sufficient to track normal speech signals. The $1 \mu \mathrm{~A}$ current sunk by TENV or RENV corresponds to a maximum fall-slope of $0.7 \mathrm{~dB} / \mathrm{ms}$. This is sufficient for a smooth envelope and also eliminates the effect of echoes on switching behaviour.

Hands free IC

To determine the noise level, the signals on TENV and RENV are buffered to TNOI and RNOI. These buffers have a maximum source current of $1 \mu \mathrm{~A}$ and a maximum sink current of $120 \mu \mathrm{~A}$. Together with the capacitors $\mathrm{C}_{\text {TNOI }}$ and $\mathrm{C}_{\text {RNOI }}$, the timing can be set. In the basic application of Fig. 13 the value of both capacitors is $4.7 \mu \mathrm{~F}$. At room temperature, the $1 \mu \mathrm{~A}$ sourced current corresponds to a maximum rise-slope of the noise envelope of approximately $0.07 \mathrm{~dB} / \mathrm{ms}$.

This is small enough to track background noise and not to be influenced by speech bursts. The $120 \mu \mathrm{~A}$ current that is sunk corresponds to a maximum fall-slope of approximately $8.5 \mathrm{~dB} / \mathrm{ms}$. However, during the decrease of the signal envelope, the noise envelope tracks the signal envelope so it will never fall faster than approximately $0.7 \mathrm{~dB} / \mathrm{ms}$. The behaviour of the signal envelope and noise envelope monitors is illustrated in Fig.8.

The pin numbers given in parenthesis refer to the TEA1094A.
Fig. 7 Signal and noise envelope detectors.

## Decision logic: pins IDT and SWT

The pin numbers given in parenthesis refer to the TEA1094A.
(1) When MUTET $=\mathrm{HIGH},+10 \mu \mathrm{~A}$ is forced.

When DLC/ $\overline{M U T E R}<0.2 \mathrm{~V},-10 \mu \mathrm{~A}$ is forced.
Fig. 9 Decision logic.

The TEA1094 and TEA1094A select their modes of operation (transmit, receive or idle mode) by comparing the signal and the noise envelopes of both channels. This is executed by the decision logic. The resulting voltage on pin SWT is the input for the voice-switch.

To facilitate the distinction between signal and noise, the signal is considered as speech when its envelope is more than 4.3 dB above the noise envelope. At room temperature, this is equal to a voltage difference $\mathrm{V}_{\mathrm{ENV}}-\mathrm{V}_{\mathrm{NOI}}=13 \mathrm{mV}$. This so called speech/noise threshold is implemented in both channels.

The signal on MIC contains both speech and the signal coming from the loudspeaker (acoustic coupling). When receiving, the contribution from the loudspeaker overrules the speech.

As a result, the signal envelope on TENV is formed mainly by the loudspeaker signal. To correct this, an attenuator is connected between TENV and the TENV/RENV comparator. Its attenuation equals that applied to the microphone amplifier.

When a dial tone is present on the line, without monitoring, the tone would be recognized as noise because it is a signal with a constant amplitude. This would cause the TEA1094 (TEA1094A) to go into the idle mode and the user of the set would hear the dial tone fade away. To prevent this, a dial tone detector is incorporated which, in standard applications, does not consider input signals between RIN1 and RIN2 as noise when they have a level greater than 127 mV (RMS). This level is proportional to $\mathrm{R}_{\text {RSEN }}$.

As can be seen from Fig.9, the output of the decision logic is a current source. The logic table gives the relationship between the inputs and the value of the current source. It can charge or discharge the capacitor $\mathrm{C}_{S W T}$ with a current of $10 \mu \mathrm{~A}$ (switch-over). If the current is zero, the voltage on SWT becomes equal to the voltage on IDT via the high-ohmic resistor $\mathrm{R}_{\text {IDT }}$ (idling). The resulting voltage difference between SWT and IDT determines the mode of the TEA1094 (TEA1094A) and can vary between -400 and +400 mV (see Table 1).

Table 1 Modes of TEA1094; TEA1094A

| $\mathbf{V}_{\mathbf{S W T}}-\mathbf{V}_{\text {IDT }}(\mathbf{m V})$ | MODE |
| :--- | :--- |
| $<-180$ | transmit mode |
| 0 | idle mode |
| $>180$ | receive mode |

The switch-over timing can be set with $\mathrm{C}_{S W T}$, the idle mode timing with $\mathrm{C}_{\text {SWT }}$ and $\mathrm{R}_{\text {IDTT }}$. In the basic application given in Fig.13, $\mathrm{C}_{\text {SWT }}$ is 220 nF and $\mathrm{R}_{\text {IDT }}$ is $2.2 \mathrm{M} \Omega$. This enables a switch-over time from transmit to receive mode or vice-versa of approximately 13 ms ( 580 mV swing on SWT). The switch-over time from idle mode to transmit mode or receive mode is approximately $4 \mathrm{~ms}(180 \mathrm{mV}$ swing on SWT).

The switch-over time, from receive mode or transmit mode to idle mode, is equal to $4 \times \mathrm{R}_{\text {IDT }} \mathrm{C}_{S W T}$ and is approximately 2 seconds (idle mode time).
The inputs MUTET and DLC/MUTER overrule the decision logic. When MUTET goes HIGH, the capacitor $\mathrm{C}_{\text {SWT }}$ is charged with $10 \mu \mathrm{~A}$ thus resulting in the receive mode. When the voltage on pin DLC/MUTER goes lower than 0.2 V , the capacitor $\mathrm{C}_{S W T}$ is discharged with $10 \mu \mathrm{~A}$ thus resulting in the transmit mode.

## VOICE-SWITCH: PINS STAB AND SWR

A diagram of the voice-switch is illustrated in Fig.10. With the voltage on SWT, the TEA1094 (TEA1094A) voice-switch regulates the gains of the transmit and the receive channel so that the sum of both is kept constant.

In the transmit mode, the gain of the microphone amplifier is at its maximum and the gain of the loudspeaker amplifier is at its minimum. In the receive mode, the opposite applies. In the idle mode, both microphone and loudspeaker amplifier gains are halfway.

The difference between maximum and minimum is the so called switching range. This range is determined by the ratio of $R_{S W R}$ and $R_{\text {STAB }}$ and is adjustable between 0 and 52 dB . R $\mathrm{R}_{\text {StAB }}$ should be $3.65 \mathrm{k} \Omega$ and sets an internally used reference current. In the basic application diagram given in Fig.13, $\mathrm{R}_{\text {SWR }}$ is $365 \mathrm{k} \Omega$ which results in a switching range of 40 dB . The switch-over behaviour is illustrated in Fig. 11.

In the receive mode, the gain of the loudspeaker amplifier can be reduced using the volume control. Since the voice-switch keeps the sum of the gains constant, the gain of the microphone amplifier is increased at the same time (see dashed curves in Fig.11). In the transmit mode, however, the volume control has no influence on the gain of the microphone amplifier or the gain of the loudspeaker amplifier. Consequently, the switching range is reduced when the volume is reduced. At maximum reduction of volume, the switching range becomes 0 dB .

## SOLDERING

## Introduction

There is no soldering method that is ideal for all IC packages. Wave soldering is often preferred when through-hole and surface mounted components are mixed on one printed-circuit board. However, wave soldering is not always suitable for surface mounted ICs, or for printed-circuits with high population densities. In these situations reflow soldering is often used.

This text gives a very brief insight to a complex technology. A more in-depth account of soldering ICs can be found in our "IC Package Databook" (order code 9398652 90011).

## DIP

## Soldering by dipping or by wave

The maximum permissible temperature of the solder is $260^{\circ} \mathrm{C}$; solder at this temperature must not be in contact with the joint for more than 5 seconds. The total contact time of successive solder waves must not exceed 5 seconds.

The device may be mounted up to the seating plane, but the temperature of the plastic body must not exceed the specified maximum storage temperature ( $\mathrm{T}_{\mathrm{stg} \max }$ ). If the printed-circuit board has been pre-heated, forced cooling may be necessary immediately after soldering to keep the temperature within the permissible limit.

## Repairing soldered joints

Apply a low voltage soldering iron (less than 24 V ) to the lead(s) of the package, below the seating plane or not more than 2 mm above it. If the temperature of the soldering iron bit is less than $300^{\circ} \mathrm{C}$ it may remain in contact for up to 10 seconds. If the bit temperature is between 300 and $400^{\circ} \mathrm{C}$, contact may be up to 5 seconds.

## SO and SSOP

## Reflow soldering

Reflow soldering techniques are suitable for all SO and SSOP packages.
Reflow soldering requires solder paste (a suspension of fine solder particles, flux and binding agent) to be applied to the printed-circuit board by screen printing, stencilling or pressure-syringe dispensing before package placement.

Several techniques exist for reflowing; for example, thermal conduction by heated belt. Dwell times vary between 50 and 300 seconds depending on heating
method. Typical reflow temperatures range from 215 to $250^{\circ} \mathrm{C}$.

Preheating is necessary to dry the paste and evaporate the binding agent. Preheating duration: 45 minutes at $45^{\circ} \mathrm{C}$.

Wave soldering
Wave soldering is not recommended for SSOP packages. This is because of the likelihood of solder bridging due to closely-spaced leads and the possibility of incomplete solder penetration in multi-lead devices.

If wave soldering cannot be avoided, the following conditions must be observed:

- A double-wave (a turbulent wave with high upward pressure followed by a smooth laminar wave) soldering technique should be used.
- The longitudinal axis of the package footprint must be parallel to the solder flow and must incorporate solder thieves at the downstream end.

## Even with these conditions, only consider wave soldering SSOP packages that have a body width of 4.4 mm , that is SSOP16 (SOT369-1) or SSOP20 (SOT266-1).

During placement and before soldering, the package must be fixed with a droplet of adhesive. The adhesive can be applied by screen printing, pin transfer or syringe dispensing. The package can be soldered after the adhesive is cured.

Maximum permissible solder temperature is $260^{\circ} \mathrm{C}$, and maximum duration of package immersion in solder is 10 seconds, if cooled to less than $150^{\circ} \mathrm{C}$ within 6 seconds. Typical dwell time is 4 seconds at $250^{\circ} \mathrm{C}$.
A mildly-activated flux will eliminate the need for removal of corrosive residues in most applications.

## Repairing soldered Joints

Fix the component by first soldering two diagonallyopposite end leads. Use only a low voltage soldering iron (less than 24 V ) applied to the flat part of the lead. Contact time must be limited to 10 seconds at up to $300^{\circ} \mathrm{C}$. When using a dedicated tool, all other leads can be soldered in one operation within 2 to 5 seconds between
270 and $320^{\circ} \mathrm{C}$.

## DEFINITIONS

| Data sheet status |  |
| :--- | :--- |
| Objective specification | This data sheet contains target or goal specifications for product development. |
| Preliminary specification | This data sheet contains preliminary data; supplementary data may be published later. |
| Product specification | This data sheet contains final product specifications. |
| Limiting values | Limiting values given are in accordance with the Absolute Maximum Rating System (IEC 134). Stress above one or <br> more of the limiting values may cause permanent damage to the device. These are stress ratings only and operation <br> of the device at these or at any other conditions above those given in the Characteristics sections of the specification <br> is not implied. Exposure to limiting values for extended periods may affect device reliability. |
| Application information |  |
| Where application information is given, it is advisory and does not form part of the specification. |  |

## LIFE SUPPORT APPLICATIONS

These products are not designed for use in life support appliances, devices, or systems where malfunction of these products can reasonably be expected to result in personal injury. Philips customers using or selling these products for use in such applications do so at their own risk and agree to fully indemnify Philips for any damages resulting from such improper use or sale.
